

## Reconstructing discontinuities in multivariate data

[The following text is heavily obscured by horizontal black bars and is largely illegible. It appears to be the main body of a paper or report.]

Fig. 1. Adding a smooth function changes neither the location nor the size of a jump discontinuity.

For a given point of reconstruction  $x$  and fixed source position  $\eta$ , we integrate the scattered field along the time-distance surface (curve in the 2-D case)  $t = \phi^{\text{in}}(x, \eta) + \phi^{\text{out}}(x, \xi)$ , which is dictated by the background index of refraction  $n_0(x)$ . It is clear that if there were a reflector at the point  $x$ , along this curve the scattered field is most affected. The weight function  $b(x, \xi)$  in Eq. (3) is chosen so that we recover the jump of the function  $f$  at the point  $x$  as a result of such integration. The weight function  $b(x, \xi)$  depends on
