

## 2. Method of Calculations

The calculation scheme is based on the following principle:

1)  $\Delta E(\alpha, \rho)$  calculations

$$\Delta E(\alpha, \rho) = \Delta E(\alpha, \rho_0) + p_{T_0} \mu_{\alpha} + p_{T_0} \mu_{\rho} - p_T \mu_{\alpha} - p_T \mu_{\rho}$$

where  $\rho_0 = \rho_{T_0}$  is the density at the initial temperature  $T_0$ .

$$\Delta H_{\text{f}}(\text{CuInSe}_2) = \frac{\partial \Delta H_{\text{f}}}{\partial z_{\text{CuSe}}} \quad (5)$$

formation of binaries

from the elemental sulfur (and thus by the values that will cause (e.g.,  $\text{In}_2\text{Se}_3$  and  $\text{Cu}_2\text{Se}$ ).

obtained from the diagram is the value of the defect enthalpy that is given in the literature (e.g.,  $\Delta H_{\text{f}}(\text{CuInSe}_2) = -120 \text{ kJ/mol}$ ) and is equal to the value obtained from the diagram.

$$-\Delta E(\alpha'_1) = \Delta E(\alpha_1) + \Delta E(\alpha'_2) - \Delta E(\alpha_2) \quad (6)$$

The calculated values of the defect enthalpies are given in Table I. The calculated values are given in Table I.

Table 1 Defect formation energies,  $\Delta E(\text{eV})$ , in  $\text{K}_{0.3}\text{Fe}_2\text{O}_3$  and defect transition probabilities.

This image is a high-contrast, black-and-white scan or digital representation of a surface. The top portion is predominantly black with sparse, isolated white pixels. The bottom portion is characterized by several horizontal bands of different patterns. From left to right, there are bands of solid black, white with black speckles, and various noise patterns such as horizontal lines and small dots. The overall texture is grainy and suggests a low-quality scan of a physical object.

where  $m = 1, 2$ .

The analysis shows that the energy barrier for interaction and driving energies  $\Delta H_f^0$  and  $\Delta H_f^0 + \Delta E_{\text{corr}}$  for the direct nanoparticle array ( $2V_2^- + In^{2+}$ ) is about  $-1.4 \text{ eV}$ , which is lower than  $\Delta H_f^0(V_{Cu}^{+})$  of the 6 nm size particles at the same temperature. It is interesting to note that  $\Delta H_f^0(2V_2^-) = -4.5 \text{ eV}$  at point A in Fig. 7. The total energy barrier through the depth of the array could be as low as  $-6.1 \text{ eV}$  at point B. Thus, spontaneous formation of stable

For isolated interacting ( $2V_{Cu}^- + In_{Cu}^{z+}$ ) pair, we find that the pairing pushes up the  $In_{Cu}^-$  levels to positions much closer to the Fermi level than the minimum of the  $V_{Cu}^-$  band.
