Figure 1. A composite image showing the distribution of the three main components of the magnetic field in the solar corona. The left panel shows the vertical component of the magnetic field (B_z) in G, with a color scale from -10 to 10. The right panel shows the horizontal component (B_x) in G, with a color scale from -10 to 10. The background is a grayscale image of the solar disk.

Figure 10. The first three rows show the results of the proposed method for the first three images in the test set. The last row shows the results of the proposed method for the first three images in the test set.

After the first few days of the experiment, the researchers found that the subjects' performance improved significantly.

Figure 1. A composite of three panels showing the spatial distribution of the first three principal components of the first 1000 samples of the training set.

Figure 1. A schematic diagram of the experimental setup. The inset shows the optical micrograph of the sample area.

Figure 10. A 2D visualization of the learned features from the first layer of the network. The features are visualized as a heatmap where each pixel corresponds to a feature vector. The colors represent the magnitude of the features.

Figure 1. A schematic diagram of the experimental setup. The inset shows the optical micrograph of the sample area.

Figure 1. A 2D heatmap showing the distribution of the first principal component (PC1) across the brain regions. The color scale indicates the magnitude of PC1, ranging from -0.5 (blue) to 0.5 (red). The heatmap shows a clear spatial pattern where PC1 is positive in the posterior regions and negative in the anterior regions.

Figure 1. The first two panels show the spatial distribution of the total flux density of the γ -ray source at 10 GeV. The third panel shows the flux density of the source at 10 GeV.

and 'negative' radio

Figure 10. The effect of the number of hidden neurons on the performance of the proposed model.

Figure 1. A schematic diagram of the experimental setup. The sample is placed in a vacuum chamber, which is connected to a vacuum system. The sample is heated by a resistive heating element, and its temperature is monitored by a thermocouple. The sample is also connected to a pressure sensor.

Figure 1. A schematic diagram of the experimental setup. The light source (laser) emits light through a lens and beam splitter. The beam splitter splits the light into two paths: one path goes through a polarizer and a lens to a photomultiplier tube (PMT), and the other path goes through a lens to a camera.

Figure 1. A schematic diagram of the experimental setup for the measurement of the absorption coefficient of the sample.

(Received 12 January 1993; accepted 12 April 1993)

Key words: Coelophysis bauri, bill length, bill acidity, environmental acidification, Permian, West Texas.

Introduction—The Permian period was a time of significant environmental change, particularly in the late Permian, when the Earth experienced the largest mass extinction ever recorded (Koch et al., 1990).

The Permian period was characterized by a global arid climate, which led to the formation of large deserts and

extensive salt deposits (Koch et al., 1990). The Permian period also saw the rise of the first true mammals, the first birds, and the first flowering plants (Koch et al., 1990).

The Permian period ended with the largest mass extinction ever recorded, known as the Permian-Triassic extinction event (Koch et al., 1990).
